From Cash Transfers to Market Linkages: A Cross-National Assessment of Agricultural Support for Farmers and Consumers

Deconstructing Three Models of State Intervention

A comparative examination of state-led agricultural interventions reveals a spectrum of policy instruments designed to address the multifaceted challenges facing smallholder farmers and consumers. This analysis focuses on three distinct models: Bangladesh's 'Sufal Bangla', a market-linkage intervention; West Bengal's 'Krishak Bandhu', a direct income support scheme; and China's macro-micro simulation framework, a tool for policy impact assessment. Each model embodies a different philosophy on how best to achieve agricultural development goals, ranging from building institutional capacity and improving market infrastructure to providing direct financial transfers and simulating complex economic scenarios.

Bangladesh's 'Sufal Bangla' represents a supply-side, market-enhancement approach aimed at strengthening the entire value chain for small-scale agricultural producers [19]. Its core mechanism is not a direct financial subsidy but the creation of institutional structures, likely Farmer Producer Companies (FPCs) or similar cooperatives, to aggregate produce from numerous smallholders [15] [95]. By consolidating smaller quantities of produce, these entities can overcome the challenge of scale economies in production, packaging, and marketing, which often hinders individual small-scale farmers [96]. The project management unit oversees the enrollment, supervision, and monitoring of activities undertaken by these groups [16]. The stated objectives are comprehensive, aiming for sustainable livelihoods through improved decision-making, knowledge management, and enhanced income generation [19]. A central goal is to improve food security and nutrition by ensuring that farmers can successfully bring their products to market and receive fair returns [20]. This model is predicated on the idea that poverty alleviation and rural development are best achieved by integrating smallholders into more efficient and profitable market systems, rather than relying solely on direct aid. The involvement of institutions like the World Bank suggests a focus on principles of private

sector development and sustainable business practices, where the role of the state is to build the enabling environment for market actors to thrive [101][103].

In stark contrast, West Bengal's 'Krishak Bandhu' (Friend of the Farmer) is a demand-side, income-smoothing policy implemented as a direct cash transfer program [45][136]. Launched in the 2019 state budget, the scheme provides an assured income to registered farmers, functioning as a form of output-based aid linked to cultivation activity or landholding [94][136]. Its primary objective is to provide a financial safety net, allowing farmers to absorb risks associated with crop failures, price volatility, and other production-related shocks [1][40]. By guaranteeing a minimum level of income, the scheme aims to cover basic household food and non-food expenses, thereby preventing distress sales of assets and maintaining the continuity of agricultural investment [17][24]. The design of Krishak Bandhu shows notable inclusivity, as it extends benefits to registered tenant-farmers, a rare feature that broadens its reach beyond land-owning households and acknowledges the rights of sharecroppers who have historically been marginalized [94]. Furthermore, the scheme incorporates elements of productivity enhancement by including provisions for agricultural inputs, such as water-saving irrigation kits branded as 'Krishak Bandhu', which can save farmers between 30% and 50% of their water usage [63]. This dual focus on immediate income support and long-term productivity improvement distinguishes it from pure unconditional cash transfer programs.

The third model, China's approach to agricultural subsidy reform analysis, is not an implemented policy itself but a sophisticated analytical framework used for policy evaluation and scenario planning [3][4]. This methodology integrates Computable General Equilibrium (CGE) models, which capture economy-wide interactions and feedback loops, with microsimulation models that track impacts at the granular level of individual households [9][10][61]. This coupled approach allows researchers to decompose overall welfare changes into their constituent parts, such as changes in income, shifts in consumption patterns due to price changes, and effects on employment [9]. The objective of this exercise is to rigorously quantify the potential outcomes of various hypothetical policy reforms before they are enacted. This includes assessing the likely impacts on farm incomes, consumer welfare (particularly through changes in food prices), the distribution of income across different socioeconomic groups, and even environmental externalities [3][6][7]. The extensive use of this integrated modeling technique indicates a highly data-driven and evidence-based approach to policymaking in China [111]. It moves beyond anecdotal evidence to provide policymakers with quantitative estimates of the trade-offs involved in different policy choices, such as the effect of eliminating subsidies on producer and consumer welfare or the potential for targeted subsidies to reduce regional

inequalities [124148]. This proactive, simulation-based strategy serves as a powerful tool for mitigating downside risks and enhancing the feasibility of future reforms [55].

Feature	Sufal Bangla (Market-Linkage)	Krishak Bandhu (Direct Income Support)	China's Subsidy Reform Simulation
Primary Mechanism	Institutional aggregation (e.g., FPCs), logistics, and market facilitation [15] [16]	Direct cash transfer to registered farmers [45] [94]	Integrated CGE-Microsimulation modeling of policy scenarios [9] [10]
Core Objective	Enhance value chains, reduce post-harvest losses, and improve market access [19] [95]	Provide risk absorption, ensure minimum income, and mitigate shocks [1] [40]	Quantify welfare impacts (producer/consumer/income/inequality) of potential reforms [3] [6]
Target Beneficiaries	Smallholder farmers, organized into collective units [15]	Registered cultivators, including tenant farmers [94]	Modeled at the household level across different income quintiles [6]
Nature of Intervention	Supply-side, institutional development	Demand-side, income smoothing	Analytical, predictive, and evaluative
Key Differentiator	Focus on overcoming market failures and scale barriers	Focus on financial risk management and liquidity	Use of advanced modeling to de-risk policy decisions

Comparative Analysis of Farmer Welfare Outcomes

The effectiveness of state-led agricultural policies in enhancing the welfare of smallholder farmers can be assessed through several critical lenses: direct income generation, risk mitigation, and long-term productivity gains. The 'Sufal Bangla', 'Krishak Bandhu', and China's subsidy regimes each pursue these objectives through fundamentally different pathways, yielding distinct sets of outcomes and challenges.

The 'Krishak Bandhu' scheme in West Bengal offers a straightforward and potent mechanism for direct income support. By providing an assured income, it directly addresses the precarious financial situation of many farmers, enabling them to meet basic household needs for food and non-food expenses [17]. This direct infusion of cash is particularly effective for risk absorption during adverse events such as the COVID-19 pandemic, which led to widespread unemployment and reduced household income [21]. Studies utilizing Likert scale surveys indicate that farmers perceive such income security schemes positively, associating them with improved livelihoods and greater stability [38] [41] [42] [43] [46] [47]. The scheme's ability to help farmers cope with crises is evident in cases where it provided crucial financial assistance despite significant revenue losses from other sources, such as a 68% drop in leaf sales for some farmers [39] [98]. The co-existence of 'Krishak Bandhu' with national schemes like PM-KISAN is seen as synergistic,

collectively strengthening farmers' capacity to absorb farming-related risks [1] [40] [44]. However, while effective at stabilizing household consumption, the long-term impact of Krishak Bandhu on pushing farmers toward commercialization or increasing their productive assets remains less clear compared to market-oriented interventions. Its primary strength lies in its immediacy and simplicity as a shock absorber.

In contrast, the 'Sufal Bangla' model aims for higher and more sustainable income growth by tackling structural inefficiencies in the agricultural value chain. Instead of a direct handout, it invests in building institutional capacity, primarily through the formation of Farmer Producer Companies (FPCs) [15]. These collectives allow smallholders to pool resources, negotiate better prices, and access markets that would otherwise be inaccessible due to their fragmented nature [95]. If successful, this approach can lead to tangible improvements in household income and dietary diversity, as cooperative membership has been shown to significantly increase both [102]. The model also seeks to reduce post-harvest losses, which are a major source of income erosion for small farmers [96]. However, the effectiveness of this model is entirely contingent on flawless execution. The establishment of functional FPCs requires strong leadership, transparent governance, and robust logistical support, areas where such organizations often face significant managerial challenges [57]. Empirical evidence from impact evaluations globally shows that a substantial portion of agricultural interventions—about 41 percent—can lead to negative or nonsignificant impacts on farm yields or household income, highlighting the high risk of failure associated with complex, implementation-heavy projects [100]. Therefore, while 'Sufal Bangla' holds the promise of transformative, market-driven growth, its success is not guaranteed and depends heavily on overcoming formidable "last mile" implementation hurdles.

China's experience with agricultural subsidies, analyzed through simulation models, presents a nuanced picture of income effects. On one hand, subsidies have been empirically demonstrated to significantly raise the per capita income of rural households and play a crucial role in reducing income inequality between them [6] [162]. This aligns with the general finding that agricultural growth has a strong poverty-reducing impact [24]. However, the same models reveal potential downsides. For instance, input subsidies can stimulate production so effectively that they lead to an oversupply of agricultural goods, which can depress prices and potentially harm farmer profitability if not managed correctly [26]. The simulations highlight the complex interplay between production incentives and market dynamics. Removing subsidies, as was done in New Zealand in the mid-1980s, had a range of sustainable development-related effects, demonstrating that such policies create new economic equilibria [117]. The Chinese context, characterized by a long tradition of smallholder farming, means that the distributional impact of any subsidy

reform is profound, as it involves a significant transfer of income within the rural economy [79] [80]. The simulation approach allows for a careful calibration of these effects, seeking to maximize income gains for farmers while minimizing distortions and negative externalities.

Assessing Consumer Welfare and Food Security Implications

The ultimate success of agricultural policies is measured not only by their impact on producers but also by their contribution to consumer welfare and national food security. The three models under review—'Sufal Bangla', 'Krishak Bandhu', and China's subsidy regime—pursue these goals through divergent mechanisms, creating distinct and sometimes conflicting implications for consumers.

The 'Krishak Bandhu' scheme, being a direct producer subsidy, has no immediate or direct effect on consumer food prices. Its primary channel to consumers is indirect: by providing a stable income floor for farmers, it helps maintain agricultural production levels and prevents drastic reductions in supply that could trigger sharp price hikes during periods of low output or market disruption [35]. This contributes to price stability and enhances food security by ensuring a consistent supply of agricultural products. The logic is that financially secure farmers are more likely to continue producing, thus safeguarding the nation's food basket [24]. While the scheme does not directly lower prices for consumers, its role in stabilizing the supply side can be viewed as a form of implicit support to consumer welfare, especially for low-income groups who spend a large proportion of their income on food [82].

The 'Sufal Bangla' model, conversely, has a more direct and potentially positive impact on consumer welfare through increased market efficiency. By focusing on improving logistics, cold storage, and market linkages, the program aims to reduce the significant post-harvest losses that plague smallholder systems [121]. Minimizing these losses increases the total quantity of food available for consumption, which, all else being equal, can exert downward pressure on retail prices and improve affordability for consumers [121]. Furthermore, by connecting farmers directly to buyers, including public distribution systems, the model can eliminate layers of intermediaries, whose markups contribute to higher final prices [139]. The emphasis on quality control and standardized packaging can also enhance the value proposition for consumers. Ultimately, the 'Sufal Bangla' initiative

contributes to food security by making the entire food system more resilient and efficient, from farm to fork [20]. This contrasts with policies that focus narrowly on either production support or consumption subsidies, as it seeks to optimize the entire supply chain.

China's agricultural subsidy policies present the most complex set of trade-offs for consumer welfare, a relationship that is extensively modeled using computable general equilibrium (CGE) frameworks [32] [159]. Input subsidies, such as those for fertilizer or machinery, can benefit consumers by lowering production costs for farmers, which may translate into lower food prices [53]. Conversely, output subsidies or price support mechanisms, like Minimum Support Prices (MSP), are designed to protect farmer incomes but can impose a direct cost on consumers by keeping domestic food prices artificially high above world market levels [35] [137]. Simulations are crucial for quantifying these opposing forces. For example, research has shown that a 10 percent increase in domestic food prices can push a significant number of people into poverty, underscoring the sensitivity of consumer welfare to price changes [143]. CGE models allow policymakers to explore these dynamics, analyzing how different subsidy structures affect the balance between producer and consumer surplus [159]. The primary goal of Chinese agricultural policy is to guarantee national food security and the supply of major agricultural products, and simulations help navigate the path to achieving this goal without unduly burdening consumers or distorting international trade [147][153]. The analysis also considers the environmental dimension, recognizing that policies promoting intensive farming can have long-term consequences for resource sustainability, which in turn affects future food security [28] [91].

Aspect	Sufal Bangla	Krishak Bandhu	China's Subsidy Regime
Effect on Consumer Prices	Potentially lowers prices by reducing post-harvest losses and transaction costs [121].	No direct effect; supports price stability by maintaining supply [35].	Highly dependent on subsidy type; input subsidies may lower prices while output subsidies may raise them [32] [35].
Impact on Consumer Welfare	Indirectly improves welfare through lower prices and a more reliable supply chain [121].	Indirectly supports welfare by ensuring stable food supply and preventing price spikes [35].	Complex and model-dependent; involves trade-offs between producer support and consumer burden [143][159].
Contribution to Food Security	Enhances system efficiency and reduces waste, contributing to availability and access [20].	Ensures farmers' capacity to produce, securing the supply base [24].	Explicitly central to policy; simulations assess impacts of trade and domestic policies on food access [69] [147].
Primary Channel to Consumers	Improved market efficiency and logistics.	Supply-side stabilization and income support for producers.	Economy-wide price and income adjustments modeled via CGE frameworks.

Evaluating Policy Effectiveness and Structural Feasibility

Beyond welfare outcomes, the practical viability and long-term sustainability of agricultural policies depend critically on their structural design, including targeting accuracy, administrative feasibility, and fiscal cost. A comparative analysis reveals fundamental differences in the operational requirements and potential pitfalls of each model.

The 'Sufal Bangla' model, centered on institutional aggregation, faces high implementation complexity. Its success is not merely a matter of funding but hinges on the successful formation and sustained operation of Farmer Producer Companies (FPCs) [15]. These entities must be capable of managing logistics, quality control, market negotiations, and internal governance—all tasks that require significant technical expertise and organizational maturity [57]. The reliance on such collective action introduces risks of corruption, mismanagement, and unequal power dynamics within the groups [57]. The project's success is therefore contingent on building robust social capital and administrative capacity at the grassroots level, a process that can be slow and fraught with challenges. While the World Bank has supported similar projects focused on improving agricultural production and food security, the transition from a well-designed project document to sustained, effective farmer-led enterprises is a significant hurdle [101] [140]. The feasibility of 'Sufal Bangla' is therefore strongly correlated with the pre-existing institutional environment and the state's capacity to provide ongoing technical and financial support.

In contrast, the 'Krishak Bandhu' scheme is structurally simpler to implement, as it relies on a direct cash transfer mechanism. This reduces the need for complex market intermediaries or the management of physical assets. The primary administrative task is the maintenance of an accurate and up-to-date database of registered farmers and the efficient disbursement of funds. However, this simplicity brings its own set of challenges, particularly regarding targeting accuracy and fiscal sustainability. While the inclusion of tenant farmers is a progressive feature [94], ensuring that payments reach genuine smallholders and do not leak to ineligible beneficiaries or larger, wealthier farmers is a persistent problem in cash transfer programs worldwide. One source presents a particularly concerning and counterintuitive finding: access to the Krishak Bandhu scheme was found to be *positively associated* with increased vulnerability among some households [78]. This anomaly suggests potential unintended consequences, such as moral hazard, reduced incentive to diversify income sources, or flaws in the targeting

mechanism that inadvertently benefits the most vulnerable rather than shielding them. From a fiscal perspective, universal or broadly targeted cash transfer schemes can become very expensive over time, posing a significant long-term burden on state budgets, especially in developing countries [124].

China's approach, through its macro-micro simulation framework, does not represent an implemented policy but rather a methodological tool to evaluate the feasibility and consequences of various policy options before implementation [55]. The true test of a policy's feasibility is whether it can be implemented effectively on the ground, and this modeling approach helps anticipate potential problems. For example, simulations can reveal the political economy challenges of removing subsidies that are deeply entrenched in the system [148]. The framework allows policymakers to analyze the distributional consequences and identify strategies to manage the transition, thereby enhancing the real-world feasibility of reforms [55]. This proactive analysis is complemented by efforts to improve administrative data integrity, as digital testing has been shown to sharply reduce the risk of errors and fraud in large-scale government programs [125]. The combination of rigorous simulation and robust administrative systems represents a high-capacity approach to policy design, prioritizing evidence and risk mitigation over ad-hoc implementation. This stands in contrast to contexts where the lack of reliable data can be a binding constraint to scaling up effective reforms [125].

Structural Dimension	Sufal Bangla	Krishak Bandhu	China's Subsidy Reform Simulation
Implementation Complexity	High; requires building strong local institutions (FPCs) and managing logistics [15] [57].	Low to moderate; relies on direct cash transfer but requires a robust beneficiary registry [94].	Not applicable; it is an analytical tool that informs feasibility assessments [55].
Targeting Accuracy	Group-based; accuracy depends on internal governance of FPCs [15].	Individual-based; inclusive of tenants but susceptible to leakage and error [78] [94].	Explicitly modeled at the household level to assess differential impacts [9].
Fiscal Sustainability	Requires continuous investment in infrastructure and operations; long-term cost is significant [19].	Potentially high recurring cost depending on coverage and payout amounts [124].	Simulates the fiscal costs and budgetary implications of different reform paths [124].
Key Feasibility Challenge	Building and sustaining effective farmer collectives [57].	Ensuring accurate targeting and preventing beneficiary exclusion or inclusion errors [78].	Navigating political economy constraints and managing public acceptance of reforms [55].

Distributional Impacts and Equity Considerations

The distributional consequences of agricultural policies are paramount, as they determine whether a policy achieves its equity objectives or inadvertently exacerbates existing inequalities. The 'Sufal Bangla', 'Krishak Bandhu', and China's subsidy regimes each have unique distributional profiles shaped by their underlying mechanisms.

The 'Krishak Bandhu' scheme in West Bengal demonstrates a conscious effort towards inclusivity, a key factor in its distributional profile. By extending cash grants to registered tenant-farmers, it recognizes their crucial role in agricultural production and ensures they are not excluded from state support, a feature that is rare in many similar programs globally [94]. This makes the scheme inherently more progressive than one limited to landowners. However, the equity of a cash transfer program ultimately depends on the accuracy of its targeting mechanism. If the registration process fails to capture the most vulnerable small and marginal farmers, or if larger, more politically connected farmers are able to claim benefits, the scheme's redistributive intent can be undermined. The aforementioned finding that access to 'Krishak Bandhu' is positively associated with increased vulnerability raises serious questions about its actual impact on the poorest segments of the farming community [78]. Such a result implies that the scheme might be failing its most vulnerable targets or, more concerningly, that it could be creating dependency or altering behavior in ways that increase risk exposure. This highlights the critical importance of continuous monitoring and evaluation to understand the true distributional effects of a seemingly simple policy.

The 'Sufal Bangla' model, by operating through collective bodies like Farmer Producer Companies (FPCs), has a more ambiguous distributional impact. On one hand, it is designed to empower smallholders collectively, giving them a stronger voice in the market and potentially leading to more equitable sharing of value along the supply chain [95]. Cooperatives have been shown to significantly increase household income and improve dietary diversity, suggesting a positive impact on food security at the household level [102]. However, the internal dynamics of these collectives can lead to inequitable outcomes. Power may remain concentrated in the hands of a few influential members, or the benefits of increased income may disproportionately accrue to larger producers within the group. The distribution of gains within the FPC is not addressed in the available documentation and represents a significant gap in understanding the scheme's full equity implications. The model's focus is on the group as a whole, but the intragroup distribution of benefits is a critical determinant of its overall success in promoting equity among smallholders.

China's experience with agricultural subsidies, as revealed by macro-micro simulations, underscores the profound impact of policy design on income distribution. Research consistently shows that well-designed agricultural subsidies can be a powerful tool for raising the per capita income of rural households and, crucially, for reducing income inequality between them [6] [162]. This suggests that when structured effectively, these policies can act as a redistributive mechanism, lifting the incomes of poorer households more significantly than those of richer ones. However, the same policies can also have negative distributional consequences if not carefully managed. For instance, subsidies that artificially inflate agricultural prices can disproportionately harm low-income urban consumers who spend a large share of their budget on food [143]. Furthermore, poorly targeted subsidies can create perverse incentives, leading to inefficient resource allocation and benefiting larger, more capitalized farms at the expense of smallholders [148]. The sophistication of China's modeling approach allows for a granular analysis of these effects across different regions and household types, providing policymakers with the evidence needed to fine-tune subsidy programs to maximize their pro-poor impact. This focus on distributional consequences is increasingly recognized as essential for achieving broader goals of common prosperity and sustainable development [6] [131].

Distributional Aspect	Sufal Bangla	Krishak Bandhu	China's Subsidy Regime
Progressivity	Ambiguous; depends on internal governance of FPCs. May empower smallholders collectively but risks concentration of benefits [95].	Potentially progressive due to the inclusion of tenant farmers [94]. However, targeting errors could undermine this [78].	Can be a powerful tool for reducing rural income inequality when well-designed [6] [162].
Risk of Leakage/ Benefit Capture	High risk of internal governance issues within FPCs leading to benefit capture by influential members [57].	Moderate risk of targeting errors, where payments go to ineligible or non-farmer beneficiaries [78].	Simulations help identify vulnerable groups and design measures to protect them from negative impacts [55].
Impact on Vulnerability	Unknown; could either decrease vulnerability through stable incomes or increase it if market pressures lead to unsustainable practices.	Counterintuitively, one study found access to the scheme is positively associated with increased vulnerability [78].	Models can analyze how reforms affect different vulnerability profiles across the rural population [126].
Focus on Equity	Focuses on the collective empowerment of smallholders.	Focuses on providing a basic income floor to all eligible farmers.	Explicitly models impacts across income quintiles to inform pro-poor policy design [6].

Synthesis of Findings and Transferable Policy Lessons

The comparative analysis of Bangladesh's 'Sufal Bangla', West Bengal's 'Krishak Bandhu', and China's simulated subsidy reforms illuminates a series of critical trade-offs,

implementation challenges, and strategic considerations for policymakers. No single model emerges as universally superior; instead, the optimal choice depends heavily on a country's specific institutional capacity, market maturity, and primary development challenges. The synthesis of these diverse approaches yields several high-level, actionable insights for government consultants and development economists.

First, the choice between a direct income support mechanism and a market-linkage intervention is a fundamental policy decision reflecting different philosophies of development. 'Krishak Bandhu' offers a rapid and administratively straightforward solution for stabilizing household consumption and mitigating acute financial shocks, making it an invaluable tool during crises [1] [40]. However, its long-term efficacy in fostering commercialization and resilience is limited without complementary investments in productivity. Conversely, 'Sufal Bangla' aims for deeper, systemic change by building institutional capacity and improving market access, which can lead to more sustainable income growth [19] [95]. The most effective strategy may lie in a hybrid approach: using direct support as a temporary safety net to give farmers the security needed to participate in and benefit from longer-term market-enhancing programs. This phased approach creates a virtuous cycle where supported farmers become more resilient and less dependent on future transfers.

Second, the "last mile" problem of implementation is the decisive factor determining the real-world success of any agricultural policy. The theoretical benefits of 'Sufal Bangla' are contingent on the flawless functioning of Farmer Producer Companies, an outcome far from guaranteed given the documented managerial challenges they face [15] [57]. Similarly, the equity of 'Krishak Bandhu' hinges entirely on an accurate and corruption-free targeting and payment system, a feat complicated by findings of increased vulnerability among some recipients [78]. The primary lesson here is that policy design must be matched with an investment in administrative capacity. This includes developing transparent digital registries, ensuring data integrity through methods like digital testing [125], and establishing robust systems for independent auditing and oversight [82]. The Chinese model's strength lies in its proactive use of simulation to anticipate these implementation bottlenecks and design safeguards, a practice that should be emulated to de-risk policy rollouts [55].

Third, the inherent trade-off between supporting producer welfare and consumer welfare cannot be avoided. Policies that shield farmers from low prices, such as Minimum Support Prices, often come at the expense of consumers who face higher food bills [35] [137]. Conversely, policies aimed at maximizing consumer welfare through cheap food can squeeze farmer margins and undermine agricultural sustainability. Policymakers must

make these trade-offs explicit and deliberate. Advanced analytical tools like CGE-microsimulation are indispensable for quantifying these competing effects and designing more balanced policies [9] [159]. A promising avenue is the decoupling of support from production—for example, paying farmers for ecosystem services or for absorbing climate-related risks—thereby protecting their livelihoods without directly distorting food prices [81] [148].

Finally, the distributional impact of a policy is not an automatic outcome but the product of careful design and constant monitoring. The inclusion of tenant farmers in 'Krishak Bandhu' is a commendable step toward greater equity [94], yet the counterintuitive finding of increased vulnerability serves as a stark warning against complacency [78]. It underscores the necessity of evaluating policies not just on their average impacts but on their differential effects across various subgroups, such as small, marginal, and female-headed households. The Chinese approach of modeling impacts across different income quintiles provides a best-practice template for ensuring that agricultural policies contribute to, rather than hinder, broader goals of poverty reduction and social equity [6] [162]. In conclusion, the most effective agricultural support systems are those that combine a clear understanding of the local context, a commitment to building strong institutions, the use of evidence-based tools for policy design, and a relentless focus on achieving equitable outcomes for both producers and consumers.
